- SMO technique;
- Kernel tricks;

## Classification problem and maximum margin strategy

# Classification problem

- Given a set of samples with their category labels (denoted as  $(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \dots, (\mathbf{x}_n, y_n)$ ,  $y_i \in \{-1, +1\}$ , the goal of classification problem is to find an appropriate function  $f(\mathbf{x})$  that can describe the dependency between  $y_i$  and  $\mathbf{x}_i$ ; thus, for a new sample  $\mathbf{x}'$ , we can infer its category based on  $f(\mathbf{x}')$ .
- A great variety of classification algorithms have been designed, including Fisher's linear discriminant, logistic regression, decision tree, neural network and SVM.

# Linear classifier

- Unlike decision tree, SVM adopts the classifier with the following type:
  - If  $f(\mathbf{x}) > 0$  then  $y = +1$ ;
  - If  $f(\mathbf{x}) < 0$  then  $y = -1$ ;
- Let's first restrict the  $f(\mathbf{x})$  to be linear, i.e.

$$f(\mathbf{x}) = \omega^T \mathbf{x} + b$$

The hyperplane  $\omega^T \mathbf{x} + b = 0$  is denoted as separating hyperplane.

- The objective of training procedure is to find an appropriate setting of  $\omega$  and  $b$  such that all samples in the training set can be correctly labelled using the classifier. We will consider the tolerance of several mislabelled samples later.

# Maximum margin strategy

- There are always multiple settings of  $\omega$  and  $b$  that the corresponding classifier works perfectly on all samples. Which one should we use?
- We prefer the one such that the margin between positive and negative samples is maximized: The wider the margin is, the larger the generality performance on new samples. Thus, we need to solve the following optimization problem:

$$\begin{aligned} \min_{\omega, b} \quad & \frac{2}{\|\omega\|} \\ \text{s.t.} \quad & y_i(\omega \cdot x_i + b) - 1 \geq 0 \quad i = 1, 2, \dots, n \end{aligned}$$

- Note:
  - The restriction  $f(\mathbf{x}) > 0$  for positive sample  $x$  is implemented as  $f(\mathbf{x}) = 1$ .
  - The distance for any point  $x$  to the hyperplane  $\omega^T \mathbf{x} + b = 0$  is  $\frac{|\omega^T \mathbf{x} + b|}{\|\omega\|}$ . Thus, the margin is:  $\frac{2}{\|\omega\|}$ .

# An equivalent form with quadratic objective function

- An equivalent form is:

$$\begin{array}{ll}\min_{w,b} & \frac{1}{2} \|w\|^2 \\ \text{s.t.} & y_i(w \cdot x_i + b) - 1 \geq 0 \quad i = 1, 2, \dots, n\end{array}$$

- Question: how to solve this optimization problem subject to inequality constraints?
- Of course we solve the problem (called primal problem hereafter) directly using convex quadratic programming techniques; however, consider its dual problem will bring great benefits.
- Let's review the conditions of the optimal solution first.

## Lagrangian multiplier method, KKT conditions and Lagrangian dual

# A brief introduction to Lagrangian multiplier and KKT conditions

- It is relatively easy to optimize an objective function **without any constraint**, say:

$$\min f(\mathbf{x})$$

- But how to optimize an objective function **with equality constraints**?

$$\begin{array}{ll}\min & f(\mathbf{x}) \\ \text{s.t.} & g_i(\mathbf{x}) = 0 \quad i = 1, 2, \dots, m\end{array}$$

- And how to optimize an objective function **with inequality constraints**?

$$\begin{array}{ll}\min & f(\mathbf{x}) \\ \text{s.t.} & g_i(\mathbf{x}) = 0 \quad i = 1, 2, \dots, m \\ & h_i(\mathbf{x}) \leq 0 \quad i = 1, 2, \dots, p\end{array}$$

# Lagrangian multiplier: under **equality constraints**

- Consider the following optimization problem:

$$\begin{array}{ll}\min & f(x, y) \\ \text{s.t.} & g(x, y) = 0\end{array}$$

- Intuition: suppose  $(x^*, y^*)$  is the optimum point. Thus at  $(x^*, y^*)$ ,  $f(x, y)$  does not change when we walk along the curve  $g(x, y) = 0$ ; otherwise, we can follow the curve to make  $f(x, y)$  smaller, meaning that the starting point  $(x^*, y^*)$  is not optimum.

- So at  $(x^*, y^*)$ , the red line tangentially touches a blue contour, i.e. there exists a  $\lambda$  such that:

$$\nabla f(x, y) = \lambda \nabla g(x, y)$$

- Lagrange must have cleverly noticed that the equation above looks like partial derivatives of some larger scalar function:

$$L(x, y, \lambda) = f(x, y) - \lambda g(x, y)$$

- Necessary conditions of optimum point: If  $(x^*, y^*)$  is local optimum, then there exists  $\lambda$  such that  $\nabla L(x^*, y^*, \lambda) = 0$ .

# Understanding Lagrangian function

- Lagrangian function: a combination of the original optimization objective function and constraints:

$$L(x, y, \lambda) = f(x, y) - \lambda g(x, y)$$

- Note:  $\frac{\partial L(x, y, \lambda)}{\partial \lambda} = 0$  is essentially the equality constraint  $g(x, y) = 0$ .
- The critical point of Lagrangian  $L(x, y, \lambda)$  occurs at saddle points rather than local minima (or maxima). To utilize numerical optimization techniques, we must first transform the problem such that the critical points lie at local minima. This is done by calculating the magnitude of the gradient of Lagrangian.

# KKT conditions: under **inequality constraints**

- Consider the following optimization problem:

$$\begin{array}{ll}\min & f(\mathbf{x}) \\ \text{s.t.} & g_i(\mathbf{x}) \leq 0 \quad i = 1, 2, \dots, m\end{array}$$

**Figure:** Case 1: the optimum point lies in the curve  $g(\mathbf{x}) = 0$ . Thus Lagrangian condition  $\nabla L(\mathbf{x}^*, \lambda) = \mathbf{0}$  applies. Case 2: the optimum point lies within the region  $g(\mathbf{x}) \leq 0$ ; thus we have  $\nabla f(\mathbf{x}) = \mathbf{0}$  at  $\mathbf{x}^*$

# Understanding complementary slackness

**Figure:** Case 1: the optimum point lies in the curve  $g(\mathbf{x}) = 0$ . Thus Lagrangian condition  $\nabla L(\mathbf{x}^*, \lambda) = \mathbf{0}$  applies. Case 2: the optimum point lies within the region  $g(\mathbf{x}) \leq 0$ ; thus, we have  $\nabla f(\mathbf{x}) = 0$  at  $\mathbf{x}^*$

These two cases were summarized as the following two conditions:

- (Stationary point)  $\nabla L(\mathbf{x}^*, \lambda) = \mathbf{0}$
- (Complementary slackness)  $\lambda_i g_i(\mathbf{x}^*) = 0, i = 1, 2, \dots, m$

(Note that in case 2,  $g(\mathbf{x}^*) < 0 \Rightarrow \lambda = 0 \Rightarrow \nabla f(\mathbf{x}^*) = 0$ .)

# KKT conditions

- Lagrangian:

$$L(\mathbf{x}, \lambda) = f(\mathbf{x}) - \sum_{i=1}^m \lambda_i g_i(\mathbf{x})$$

- Necessary conditions of optimum point:

If  $\mathbf{x}^*$  is local optimum satisfying some regularity conditions, then there exists  $\lambda$  such that:

- ① (Stationary point)  $\nabla L(\mathbf{x}^*, \lambda) = \mathbf{0}$
  - ② (Primal feasibility)  $g(\mathbf{x}^*) \leq 0$
  - ③ (Dual feasibility)  $\lambda_i \leq 0, i = 1, 2, \dots, m$
  - ④ (Complementary slackness)  $\lambda_i g_i(\mathbf{x}^*) = 0, i = 1, 2, \dots, m$
- Note: KKT conditions are usually not solved directly in optimization; instead, iterative successive approximation is most often used. However, the final results should meet KKT conditions.

# Three strategies to solve an optimization problem under inequality constraints

- Solve the primal problem subject to primal feasibility;
- Solve the dual problem subject to the dual feasibility;
- Interior-point method: Complementary slackness, also called *orthogonality* by Gomory, essentially equals to the strong duality, i.e., the primal and dual problems have identical objective value. A relaxation of this condition, i.e.,  $\lambda_i g_i(\mathbf{x}^*) = \mu$ , is used in the interior point method to reflect duality gap.

## Applying Lagrangian dual to the maximum margin problem

# An example

- Primal problem:

$$\begin{array}{ll}\min & x \\ \text{s.t.} & x \geq 2 \\ & x \geq 0\end{array}$$

- Lagrangian:

$$L(x, y, z) = x - y * (x - 2) - z * x = 2y + x * (1 - y - z)$$

- Notice that when  $y \geq 0$ ,  $z \geq 0$  and  $x \geq 2$ ,  $L(x, y, z)$  is a lower bound of the primal objective function  $x$ .

- Lagrangian dual function:

$$g(y, z) = \inf_x L(x, y, z) = \begin{cases} 2y & \text{if } 1 - y - z = 0 \\ -\infty & \text{otherwise} \end{cases}$$

- Dual problem:

$$\begin{array}{ll}\max & 2y \\ \text{s.t.} & y \leq 1 \\ & y \geq 0\end{array}$$

# Lagrangian connecting primal and dual

- Observation: PRIMAL objective function  $x \geq$  Lagrangian  $\geq$  DUAL objective function  $y$  in the feasible region.

# Lagrangian dual explanation of LP duality

- Consider a LP model:

$$\begin{array}{ll}\min & \mathbf{c}^T \mathbf{x} \\ \text{s.t.} & \mathbf{Ax} \geq \mathbf{b} \\ & \mathbf{x} \geq \mathbf{0}\end{array}$$

- Lagrangian:

$$L(\mathbf{x}, \lambda, \mathbf{s}) = \mathbf{c}^T \mathbf{x} - \sum_{i=1}^m \lambda_i (a_{i1}x_1 + \dots + a_{in}x_n - b_i) - \sum_{i=1}^m s_i x_i$$

- Notice that **Lagrangian is a lower bound of the primal objective function**, i.e.  $\mathbf{c}^T \mathbf{x} \geq L(\mathbf{x}, \lambda, \mathbf{s})$ , when  $\lambda \geq \mathbf{0}$ ,  $\mathbf{s} \geq \mathbf{0}$  and  $\mathbf{x}$  is feasible.
- Furthermore we have

$$\mathbf{c}^T \mathbf{x} \geq L(\mathbf{x}, \lambda) \geq \inf_{\mathbf{x}} L(\mathbf{x}, \lambda)$$

when  $\lambda \geq \mathbf{0}$ ,  $\mathbf{s} \geq \mathbf{0}$  and  $\mathbf{x}$  is feasible.

- Denote **Lagrangian dual**  $g(\lambda, \mathbf{s}) = \inf_{\mathbf{x}} L(\mathbf{x}, \lambda, \mathbf{s})$ . The above inequality can be rewritten as:

$$\mathbf{c}^T \mathbf{x} \geq L(\mathbf{x}, \lambda, \mathbf{s}) \geq g(\lambda, \mathbf{s})$$

# Lagrangian dual explanation of LP duality cont'd

- What is the Lagrangian dual  $g(\lambda, \mathbf{s})$ ?

$$\begin{aligned} g(\lambda, \mathbf{s}) &= \inf_{\mathbf{x}} L(\mathbf{x}, \lambda, \mathbf{s}) \\ &= \inf_{\mathbf{x}} (\mathbf{c}^T \mathbf{x} - \sum_{i=1}^m \lambda_i (a_{i1}x_1 + \dots + a_{in}x_n - b_i) - \sum_{i=1}^m s_i x_i) \\ &= \inf_{\mathbf{x}} (\lambda^T \mathbf{b} + (\mathbf{c}^T - \lambda^T \mathbf{A} - \mathbf{s}^T) \mathbf{x}) \\ &= \begin{cases} \lambda^T \mathbf{b} & \text{if } \mathbf{c}^T = \lambda^T \mathbf{A} + \mathbf{s}^T \\ -\infty & \text{otherwise} \end{cases} \end{aligned}$$

- Thus  $\lambda^T \mathbf{b}$  is a lower bound of  $f(\mathbf{x})$  when  $\mathbf{c}^T = \lambda^T \mathbf{A} + \mathbf{s}^T$  and  $\mathbf{x} \geq \mathbf{0}$ .
- Note  $g(\lambda)$  is always concave even if the constraints are not convex.

# Find a tight bound

- Now let's try to find the **best** lower bound of  $f(\mathbf{x})$ .
- Thus the tight lower bound  $\max g(\lambda)$  can be described as:

$$\begin{array}{ll}\max & \lambda^T \mathbf{b} \\ \text{s.t.} & \lambda^T \mathbf{A} \leq \mathbf{c}^T \\ & \lambda \geq \mathbf{0}\end{array}$$

- Notes:
  - 1 This is actually the DUAL form of LP if replacing  $\lambda$  by  $\mathbf{y}$ ; thus, we have another explanation of DUAL variables  $\mathbf{y}$  — the Lagrangian multiplier.
  - 2 Lagrangian dual is a lower bound of the primal optimum under some conditions. In addition, Lagrangian dual is concave; thus, **the dual problem is always a convex programming problem** even if the primal problem is not a convex programming problem.

# Lagrangian dual explanation of maximum margin problem

- Primal problem:

$$\begin{aligned} \min_{w,b} \quad & \frac{1}{2} \|w\|^2 \\ \text{s.t.} \quad & y_i(w^T x_i + b) \geq 1, \quad i \in \{1, \dots, n\} \end{aligned}$$

- Lagrangian:

$$L(w, b, \alpha) = \frac{1}{2} \|w\|^2 - \sum_{i=1}^n \alpha_i y_i (w \cdot x_i + b) + \sum_{i=1}^n \alpha_i$$

- Notice that **Lagrangian is a lower bound of the primal objective function**, i.e.  $\frac{1}{2} \|w\|^2 \geq L(w, b, \alpha)$ , when  $\alpha \geq 0$  and  $w, b$  is feasible.
- Furthermore we have

$$\frac{1}{2} \|w\|^2 \geq L(w, b, \alpha) \geq \inf_{w,b} L(w, b, \alpha)$$

when  $\alpha \geq 0$  and  $w, b$  is feasible.

- Denote **Lagrangian dual**  $g(\alpha) = \inf_{w,b} L(w, b, \alpha)$ . The above inequality can be rewritten as:

$$\frac{1}{2} \|w\|^2 \geq L(w, b, \alpha) \geq g(\alpha)$$

# Lagrangian dual explanation of maximum margin duality cont'd

- What is the Lagrangian dual  $g(\alpha)$ ?

$$g(\alpha) = \inf_{w,b} L(w, b, \alpha)$$

- To calculate the inferior bound of  $L(w, b, \alpha)$ , we set its derivatives to be 0, i.e.,

$$\frac{\partial L(w, b, \alpha)}{\partial w} = w - \sum_{i=1}^n \alpha_i y_i x_i = 0$$

$$\frac{\partial L(w, b, \alpha)}{\partial b} = \sum_{i=1}^n \alpha_i y_i = 0$$

# Lagrangian dual function

- Lagrangian dual function:

$$g(\alpha) = -\frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^n \alpha_i$$

- Thus  $g(\alpha)$  is a lower bound of  $\frac{1}{2} \|w\|^2$  when  $\sum_{i=1}^n \alpha_i y_i = 0$  and  $\alpha \geq 0$ .

# Lagrangian dual problem

- Now let's try to find **the tightest lower bound** of  $\frac{1}{2} \|w\|^2$ , which can be calculated by solving the following Lagrangian dual problem:

$$\begin{array}{ll} \max & -\frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^n \alpha_i \\ \text{s.t.} & \sum_{i=1}^n \alpha_i y_i = 0 \\ & \alpha \geq 0 \end{array}$$

# Two explanations of dual variables $y$ : L. Kantorovich vs. T. Koopmans

- 1 Price interpretation: constrained optimization plays an important role in economics. Dual variables are also called as **shadow price** (by T. Koopmans), i.e. the instantaneous change in the optimization objective function when constraints are relaxed, or **marginal cost** when strengthening constraints.
- 2 **Lagrangian multiplier**: the effect of constraints on the objective function (by L. Kantorovich). For example, when  $b_i$  increase to  $b_i + \Delta b_i$ , how much the objective function value will change. In fact, we have  $\frac{\partial L(\mathbf{x}, \lambda)}{\partial b_i} = \lambda_i$ .

# Explanation of dual variables $y$ : using DIET as an example

- Optimal solution to primal problem with  $b_1 = 2000, b_2 = 55, b_3 = 800$ :  
 $\mathbf{x} = (14.24, 2.70, 0, 0)$ ,  
 $\mathbf{c}^T \mathbf{x} = 67.096$ .
- Optimal solution to dual problem:  
 $\mathbf{y} = (0.0269, 0, 0.0164)$ ,  
 $\mathbf{y}^T \mathbf{b} = 67.096$ .
- Let's make a slight change on  $\mathbf{b}$ , and watch the effect on  $\max \mathbf{c}^T \mathbf{x}$ .
  - 1  $b_1 = 2001$ :  $\max \mathbf{c}^T \mathbf{x} = 67.123$  (Note that  $y_1 = 0.0269 = 67.123 - 67.096$ )
  - 2  $b_2 = 56$ :  $\max \mathbf{c}^T \mathbf{x} = 67.096$  (Note that  $y_2 = 0 = 67.096 - 67.096$ )
  - 3  $b_3 = 801$ :  $\max \mathbf{c}^T \mathbf{x} = 67.112$  (Note that  $y_3 = 0.0164 = 67.112 - 67.096$ )

(See extra slides)

## Weak duality, strong duality, and Slater conditions

# Weak duality and strong duality

- Sometimes the optimal solution of the primal problem doesn't have identical value to that of the dual problem. The difference between them is denoted as duality gap. This case is denoted as weak duality. The opposite case is denoted as strong duality.
- Conditions under which strong duality holds are denoted as **constraint qualifications**.

# Slater's conditions for strong duality

- The best known sufficient condition of strong duality is:
  - Primal problem is convex programming, i.e.,

$$\begin{array}{ll}\min & f(\mathbf{x}) \\ \text{s.t.} & g_i(\mathbf{x}) \leq 0 \quad i = 1, 2, \dots, m \\ & \mathbf{Ax} = \mathbf{b}\end{array}$$

where  $f(x)$  and  $g_i(x)$  are convex.

- Slater's condition holds, i.e. there exists some strictly feasible point  $x \in \text{relint}(\mathcal{D})$  such that

$$\mathbf{Ax} = \mathbf{b}$$

and

$$g_i(\mathbf{b}) < 0, i = 1, 2, \dots, m$$

Here  $\mathcal{D}$  represents the feasible domain of the primal problem, and  $\text{relint}(\mathcal{D})$  denotes the relative interior of  $\mathcal{D}$ .

# Slater's conditions for strong duality (cont'd)

- The Slater's conditions are trivial if the constraints of the primal problem are affine, i.e., Consider the following convex programming problem:

$$\begin{array}{ll}\min & f(\mathbf{x}) \\ \text{s.t.} & g_i(\mathbf{x}) \leq 0 \quad i = 1, 2, \dots, m \\ & \mathbf{Ax} = \mathbf{b}\end{array}$$

where  $f(x)$  and  $g_i(x)$  are convex.

- Slater's condition: If  $g_i(x)$  are affine, the inequalities are no longer required to be strict and thus reduce to the original form, i.e. there exists some strictly feasible point  $x \in \text{relint}(\mathcal{D})$  such that

$$\mathbf{Ax} = \mathbf{b}$$

and

$$g_i(\mathbf{b}) \leq 0, i = 1, 2, \dots, m$$

# Strong duality in SVM

- For the maximum margin problem, its dual problem has the identical optimal objective function value.

Kernel method to overcome linear insperability

# Linearly inseparable

- Some samples are linearly inseparable. How should we do?
- Kernel method: If the samples are linearly inseparable in the original input space, let's map them into a higher-dimensional space (called feature space) and make them linearly separable in that space. In other words, nonlinearity was introduced into the original input space through using the map.

# An example: XOR problem

- Let's define a map:  $\phi : \mathbb{R}^2 \rightarrow \mathbb{R}^3$  as below:

$$[x^{(1)}, x^{(2)}] \rightarrow \Phi([x^{(1)}, x^{(2)}]) = [x^{(1)}, x^{(2)}, x^{(1)}x^{(2)}]$$

- These samples are linearly separable after mapping into  $\mathbb{R}^3$  using  $\Phi(x^{(1)}, x^{(2)})$

# Replace the inner product in the optimization problem for SVM

- Remember that in the optimization problem for SVM, the objective function contains inner product  $\mathbf{x}^T \mathbf{x}$ :

$$\begin{aligned} \max \quad & -\frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N \alpha_i \alpha_j y_i y_j (x_i^T x_j) + \sum_{i=1}^N \alpha_i \\ \text{s.t.} \quad & \sum_{i=1}^N \alpha_i y_i = 0 \\ & \alpha \geq 0 \end{aligned}$$

- After mapping  $\mathbf{x}$  into  $\Phi(\mathbf{x})$ , the inner product  $\mathbf{x}^T \mathbf{x}$  changes into  $\Phi(\mathbf{x})^T \Phi(\mathbf{x})$ , and the optimization problem changes accordingly:

$$\begin{aligned} \max \quad & -\frac{1}{2} \sum_{i=1}^N \sum_{j=1}^N \alpha_i \alpha_j y_i y_j (\Phi(x_i)^T \Phi(x_j)) + \sum_{i=1}^N \alpha_i \\ \text{s.t.} \quad & \sum_{i=1}^N \alpha_i y_i = 0 \\ & \alpha \geq 0 \end{aligned}$$

Note we simply replace this inner product with  $\Phi(\mathbf{x})^T \Phi(\mathbf{x})$  **without even knowing the map  $\Phi(\mathbf{x})$** .

- In other words, we define a kernel function

# The separating hyperplane

- Remember that in the optimization problem for SVM, the separating hyperplane is:

$$f(\mathbf{x}) = \omega^T \mathbf{x} + b = \sum_{i,j} \alpha_i y_i \mathbf{x}_i^T \mathbf{x} = 0$$

- After mapping  $\mathbf{x}$  into  $\Phi(\mathbf{x})$ , the separating hyperplane changes into:

$$f(\mathbf{x}) = \omega^T \Phi(\mathbf{x}) + b = \sum_{i,j} \alpha_i y_i \Phi(\mathbf{x})_i^T \Phi(\mathbf{x}) = 0$$

- Note that  $\Phi(\mathbf{x})_i^T \Phi(\mathbf{x}) = k(\Phi(\mathbf{x})_i, \Phi(\mathbf{x}))$ .

## Deriving kernel function from map

# Example 1

- Consider the map  $\Phi : \mathbb{R}^2 \rightarrow \mathbb{R}^4$ :

$$[x^{(1)}, x^{(2)}] \rightarrow \Phi([x^{(1)}, x^{(2)}]) = [x^{(1)2}, x^{(2)2}, x^{(1)}x^{(2)}, x^{(1)}x^{(2)}]$$

- The corresponding kernel function is:

$$k(\mathbf{x}, \mathbf{z}) = x^{(1)2}z^{(1)2} + x^{(2)2}z^{(2)2} + 2x^{(1)}x^{(2)}z^{(1)}z^{(2)} = \langle \mathbf{x}, \mathbf{z} \rangle_{\mathbb{R}^2}^2$$

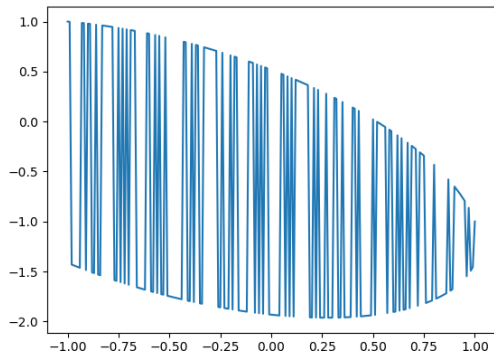

## Example 2

- Consider the map  $\Phi : \mathbb{R}^3 \rightarrow \mathbb{R}^{13}$ :

$$[x^{(1)}, x^{(2)}, x^{(3)}] \rightarrow \Phi([x^{(1)}, x^{(2)}, x^{(3)}]) = [x^{(1)2}, x^{(1)}x^{(2)}, \dots, x^{(3)2}, \sqrt{2}c]$$

- The corresponding kernel function is:

$$k(\mathbf{x}, \mathbf{z}) = \mathbf{x}^T \mathbf{z} + c$$

# The power of polynomial kernel

- We can map into a  $d$ -dimensional feature space.

# The power of polynomial kernel

## The requirement of kernel functions

# Definition of kernel function

- A function  $k : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$  is a kernel function if:
  - $k$  is symmetric:  $k(x, z) = k(z, x)$ .
  - For any  $m \in \mathbb{N}$  and any  $x_1, x_2, \dots, x_m \in \mathcal{X}$ , the matrix  $K$  defined by  $K_{i,j} = k(x_i, x_j)$  is positive semidefinite.

$$K = \begin{matrix} & \begin{matrix} 1 & j & m \end{matrix} \\ \begin{matrix} m \\ i \\ 1 \end{matrix} & \begin{bmatrix} & & \\ & k(x_i, x_j) & \\ & & \end{bmatrix} \end{matrix}$$

Question: Could we map from input space into a feature space with infinite dimension?

# Map into an infinite dimensional feature space

- Let's consider the feature space where all elements are functions.
- The span of this space is  $\Phi(x_i) = k(\cdot, x_i)$ . Thus, any element can be represented as:

$$f(\cdot) = \sum_{i=1}^m \alpha_i k(\cdot, x_i) \leftarrow \text{"vectors"}$$

- For two elements

$$\langle f, g \rangle_{H_k} = \sum_{i=1}^m \sum_{j=1}^{m'} \alpha_i \beta_j k(x_i, x'_j).$$

we define inner product as:

$$f(\cdot) = \sum_{i=1}^m \alpha_i k(\cdot, x_i) \text{ and } g(\cdot) = \sum_{j=1}^{m'} \beta_j k(\cdot, x'_j)$$

- Now we find a map such that

$$\langle k(\cdot, x), k(\cdot, x') \rangle_{H_k} = k(x, x')$$

## Theorem (Farkas lemma)

Given vectors  $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m, \mathbf{c} \in \mathbb{R}^n$ . Then either

- 1  $\mathbf{c} \in C(\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m)$ ; or
- 2 there is a vector  $\mathbf{y} \in \mathbb{R}^n$  such that for all  $i$ ,  $\mathbf{y}^T \mathbf{a}_i \geq 0$  but  $\mathbf{y}^T \mathbf{c} < 0$ .

Figure: Case 1:  $\mathbf{c} \in C(\mathbf{a}_1, \mathbf{a}_2)$       Figure: Case 2:  $\mathbf{c} \notin C(\mathbf{a}_1, \mathbf{a}_2)$

- Here,  $C(\mathbf{a}_1, \dots, \mathbf{a}_m)$  denotes the cone spanned by  $\mathbf{a}_1, \dots, \mathbf{a}_m$ , i.e.  $C(\mathbf{a}_1, \dots, \mathbf{a}_m) = \{\mathbf{x} | \mathbf{x} = \sum_{i=1}^m \lambda_i \mathbf{a}_i, \lambda_i \geq 0\}$ .

## Proof.

- Suppose for any vector  $\mathbf{y} \in \mathbb{R}^n$ ,  $\mathbf{y}^T \mathbf{a}_i \geq 0$  ( $i = 1, 2, \dots, m$ ), we always have  $\mathbf{y}^T \mathbf{c} \geq 0$ . We will show that  $\mathbf{c}$  should lie within the cone  $\mathbf{C}(\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m)$ .
- Consider the following PRIMAL problem:

$$\begin{array}{ll}\min & \mathbf{c}^T \mathbf{y} \\ \text{s.t.} & \mathbf{a}_i^T \mathbf{y} \geq 0 \quad i = 1, 2, \dots, m\end{array}$$

- It is obvious that the PRIMAL problem has a feasible solution  $\mathbf{y} = \mathbf{0}$ , and is bounded since  $\mathbf{c}^T \mathbf{y} \geq 0$ .
- Thus the DUAL problem also has a bounded optimal solution:

$$\begin{array}{ll}\max & 0 \\ \text{s.t.} & \mathbf{x}^T \mathbf{A}^T = \mathbf{c}^T \\ & \mathbf{x} \geq \mathbf{0}\end{array}$$

- In other words, there exists a vector  $\mathbf{x}$  such that  $\mathbf{c} = \sum_{i=1}^m x_i \mathbf{a}_i$  and  $x_i \geq 0$ .

# Variants of Farkas' lemma

Farkas' lemma lies at the core of linear optimization. Using Farkas' lemma, we can prove SEPARATION theorem, and MINIMAX theorem in the game theory.

## Theorem

Let  $\mathbf{A}$  be an  $m \times n$  matrix, and  $\mathbf{b} \in \mathbb{R}^m$ . Then either

- ①  $\mathbf{Ax} = \mathbf{b}$ ,  $\mathbf{x} \geq \mathbf{0}$  has a feasible solution; or
- ② there is a vector  $\mathbf{y} \in \mathbb{R}^m$  such that  $\mathbf{y}^T \mathbf{A} \geq \mathbf{0}$  but  $\mathbf{y}^T \mathbf{b} < 0$ .

## Theorem

Let  $\mathbf{A}$  be an  $m \times n$  matrix, and  $\mathbf{b} \in \mathbb{R}^m$ . Then either

- 1  $\mathbf{Ax} \leq \mathbf{b}$  has a feasible solution; or
- 2 there is a vector  $\mathbf{y} \in \mathbb{R}^m$  such that  $\mathbf{y} \geq \mathbf{0}$ ,  $\mathbf{y}^T \mathbf{A} \geq \mathbf{0}$  but  $\mathbf{y}^T \mathbf{b} < 0$ .

## Theorem

*Given vectors  $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m \in \mathbb{R}^n$ . If  $\mathbf{x} \in C(\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m)$ , then there is a linearly independent vector set of  $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_m$ , say  $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_r$ , such that  $\mathbf{x} \in C(\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_r)$ .*

## Theorem

*Let  $C \subseteq \mathbb{R}^n$  be a closed, convex set, and let  $x \in \mathbb{R}^n$ . If  $x \notin C$ , then there exists a hyperplane separating  $x$  from  $C$ .*

## Application 2: von Neumann's MINIMAX theorem on game theory

- Game theory studies competing and cooperative behaviours among intelligent and rational decision-makers.
- In 1928, John von Neumann proved the existence of mixed-strategy equilibria in two-person zero-sum games.
- In 1950, John Forbes Nash Jr. developed a criterion of mutual consistency of players' strategies, which applies to a wider range of games than that proposed by J. von Neumann. He proved the existence of Nash equilibrium in every  $n$ -player, non-zero-sum, non-cooperative game (not just 2-player, zero-sum games).
- Game theory was widely applied in mathematical economics, in biology (e.g., analysis of evolution and stability) and computer science (e.g., analysis of interactive computations and lower bound on the complexity of randomized algorithms, the equivalence between linear program and two-person zero-sum game).

# Paper-rock-scissors: an example of two-player zero-sum game

- Paper-rock-scissors is a hand game usually played by two players, denoted as row player and column player: each player selects one of the three hand shapes, including “paper”, “rock”, and “scissors”; then the players show their selections simultaneously.
- It has two possible outcomes other than tie: one player wins and the other player loses, which can be formally described using the following payoff matrix.

	Paper	Rock	Scissors
Paper	0, 0	1, -1	-1, 1
Rock	-1, 1	0, 0	1, -1
Scissors	1, -1	-1, 1	0, 0

- Each player attempts to select appropriate action to maximize his gain.

# Matching penny: another example of two-person zero-sum game

- Matching pennies is a game played by two players, namely, row player and column player. Each player has a penny and secretly turns it to head or tail. The players then reveal their selections simultaneously.
- If the pennies match, then row player keeps both pennies; otherwise, column player keeps both. The payoff matrix is as follows.

	Head	Tail
Head	1, -1	-1, 1
Tail	-1, 1	1, -1

- Each player tries to maximize his gain via making an appropriate selection.

# Simultaneous games vs. sequential games

- **Simultaneous games** are games in which all players move **simultaneously**. Thus, no player has information of the others' selections in advance.
- **Sequential games** are games in which the later player has some information, although maybe imperfect, of previous actions by the other players. A complete plan of action for every stage of the game, regardless of whether the action actually arises in play, is denoted as **a (pure) strategy**.
- **Normal form** is used to describe simultaneous games while **extensive form** is used to describe sequential games.
- J. von Neumann proposed an approach to transform strategies in sequential games into actions in simultaneous games.
- Note that the transformation is one-way, i.e., multiple sequential games might correspond to the same simultaneous game, and it may result in an exponential blowup in the size of the representation.

- A game  $\Gamma$  in normal form among  $m$  players contains the following items:
  - Each player  $k$  has a finite number of **pure strategies**  
 $S_k = \{1, 2, \dots, n_k\}$ .
  - Each player  $k$  is associated with a **payoff function**  
 $H_k : S_1 \times S_2 \times \dots \times S_m \rightarrow \mathbb{R}$ .
- To play the game, each player selects a strategy without information of others, and then reveals the selection **simultaneously**. The players' gain are calculated using corresponding payoff functions.
- Each player attempts to maximize his gain via selecting an appropriate strategy.

# Two-person zero-sum game in normal form

- In a two-person zero-sum game  $\Gamma$ , a player's gain or loss is exactly balanced by the other player's loss or gain, i.e.,

$$H_1(s_1, s_2) + H_2(s_1, s_2) = 0.$$

- Thus we can define another function

$$H(s_1, s_2) = H_1(s_1, s_2) = -H_2(s_1, s_2)$$

and represent it using a **payoff matrix**.

	Head	Tail
Head	1	-1
Tail	-1	1

- Row player aims to maximize  $H(s_1, s_2)$  by selecting an appropriate strategy  $s_1$  while column player aims to minimize  $H(s_1, s_2)$  by selecting an appropriate strategy  $s_2$ .

# von Neumann's MINIMAX theorem: motivation

- When analyzing a two-person zero-sum game  $\Gamma$ , von Neumann noticed that the difficulty comes from the difference between games and ordinary optimization problems: row player tries to maximize  $H(s_1, s_2)$ ; however, he can control  $s_1$  only as he has no information of the other player's selection  $s_2$ , and so does column player.
- Thus von Neumann suggested to investigate two auxiliary games without this difficulty, denoted as  $\Gamma_1$  and  $\Gamma_2$ , before attacking the challenging game  $\Gamma$ .
  - 1  $\Gamma_1$ : Row player selects a strategy  $s_1$  first, and exposes his selection to column player before column player selects a strategy  $s_2$ .
  - 2  $\Gamma_2$ : Column player selects a strategy  $s_2$  first, and exposes his selection to row player before row player selects a strategy  $s_1$ .
- The two auxiliary games are much easier than the original game  $\Gamma$ , and more importantly, they provide upper and lower bounds for  $\Gamma$ .

## Auxiliary game $\Gamma_1$

- Let's consider column player first. As he knows row player's selection  $s_1$ , the objective function  $H(s_1, s_2)$  becomes an ordinary optimization function over a single variable  $s_2$ , and column player can simply select a strategy  $s_2$  with the minimum objective function value  $\min_{s_2} H(s_1, s_2)$ .

	Head	Tail	Row minimum
Head	-2	1	-2
Tail	-1	2	$v_1 = -1$

- Now consider row player. When he selects a strategy  $s_1$ , he can definitely predict the selection of column player. Since  $\min_{s_2} H(s_1, s_2)$  is an ordinary function over a single  $s_1$ , it is easy for row player to select a strategy  $s_1$  with the maximum objective function value

$$v_1 = \max_{s_1} \min_{s_2} H(s_1, s_2).$$

## Auxiliary game $\Gamma_2$

- Let's consider row player first. As he knows column player's selection  $s_2$ , the objective function  $H(s_1, s_2)$  becomes an ordinary optimization function over a single variable  $s_1$ , and row player can simply select a strategy  $s_1$  with the maximum objective function value  $\max_{s_1} H(s_1, s_2)$ .

	Head	Tail
Head	-2	1
Tail	-1	2
Column maximum	$v_2 = -1$	2

- Now consider column player. When he selects a strategy  $s_2$ , he can definitely predict the selection of row player. Since  $\max_{s_1} H(s_1, s_2)$  is an ordinary function over a single variable  $s_2$ , it is easy for column player to select a strategy  $s_2$  with the minimum objective function value

$$v_2 = \min_{s_2} \max_{s_1} H(s_1, s_2).$$

# $\Gamma_1$ and $\Gamma_2$ bound $\Gamma$

- For row player, it is clearly  $\Gamma_1$  is disadvantageous to him as he should expose his selection  $s_1$  to column player.
- On the contrary,  $\Gamma_2$  is beneficial to row player as he knows column player's selection  $s_2$  before making decision.

	Head	Tail	Row minimum
Head	-2	1	-2
Tail	-1	2	$v_1 = -1$
Column maximum	$v_2 = -1$	2	

- Thus these two auxiliary games provides lower and upper bounds:

$$v_1 \leq v \leq v_2$$

where  $v$  denote row player's gain in the original game  $\Gamma$ .

## Case 1: $v_1 = v_2$

- For a game with the following payoff matrix, we have  $v_1 = v = v_2$  and call this game **strictly determined**.

	Head	Tail	Row minimum
Head	-2	1	-2
Tail	-1	2	$v_1 = -1$
Column maximum	$v_2 = -1$	2	

- The saddle point of the payoff matrix  $H(s_1, s_2)$  represents a **pure strategy equilibrium**. In this equilibrium, each player has nothing to gain by changing only his own strategy. In addition, knowing the opponent's selection will bring no gain.
- von Neumann proved the existence of the optimal strategy in a perfect information two-person zero-sum game, e.g., chess. L. S. Shapley further showed that a finite two-person zero-sum game has a pure strategy equilibrium if every  $2 \times 2$  submatrix of the game has a pure strategy equilibrium [?].

## Case 2: $v_1 < v_2$

- In contrast, matching penny does not have a pure strategy equilibrium as there is no saddle point in the payoff matrix. So does the paper-rock-scissors game.

	Head	Tail	Row minimum
Head	1	-1	-1
Tail	-1	1	$v_1 = -1$
Column maximum	$v_2 = 1$	1	

- This fact implies that knowing the opponent's selection might bring gain; however, it is impossible to know the opponent's selection as the players reveal their selections simultaneously. In this case, let's play a mixed strategy rather than a pure strategy.

# From pure strategy to mixed strategy

- A **mixed strategy** is an assignment of probability to pure strategies, allowing a player to **randomly select a pure strategy**.
- Consider the payoff matrix as below. If the row player select strategy  $A$  with probability 1, he is said to play a pure strategy. If he tosses a coin and select strategy  $A$  if the coin lands head and  $B$  otherwise, then he is said to play a mixed strategy.

	A	B
A	1	-1
B	-1	1

# Two types of interpretation of mixed strategy

- From a player's viewpoint: J. von Neumann described the motivation underlying the introduction of mixed strategy as follows: since it is impossible to exactly know opponent's selection, a player could switch to **protect himself by “randomly selecting his own strategy”**, making it difficult for the opponent to know the player's selection. However, this interpretation came under heavy fire for lacking of behaviour supports: Seldom do people make choices following a lottery.
- From opponent's viewpoint: Robert Aumann and Adam Brandenburger interpreted mixed strategy of a player as **opponent's “belief” of the player's selection**. Thus, Nash equilibrium is an equilibrium of “belief” rather than actions.

# Existence of mixed strategy equilibrium

- Consider a mixed strategy game: row player has  $m$  strategies available and he selects a strategy  $s_1$  according to a distribution  $\mathbf{u}$ , while column player has  $n$  strategies available and he selects a strategy  $s_2$  according to a distribution  $\mathbf{v}$ , i.e.,

$$\Pr(s_1 = i) = u_i, i = 1, \dots, m \quad \Pr(s_2 = j) = v_j, j = 1, \dots, n$$

Here,  $\mathbf{u}$  and  $\mathbf{v}$  are independent.

- Thus the expected gain of row player is:

$$\sum_{i=1}^m \sum_{j=1}^n u_i H_{ij} v_j = \mathbf{u}^T \mathbf{H} \mathbf{v}$$

- row player attempts to minimize  $\mathbf{u}^T \mathbf{H} \mathbf{v}$  via selecting an appropriate  $\mathbf{u}$ , while column player attempts to maximize it via selecting an appropriate  $\mathbf{v}$ .
- Now let's consider the two auxiliary games  $\Gamma_1$  and  $\Gamma_2$  again and answer the following questions: what happens if row player exposes his mixed strategy to column player? And if we reverse the order of the players?

# von Neumann's MINIMAX theorem [1928]

- This question has been answered by the von Neumann's MINIMAX theorem.

## Theorem

$$\max_{\mathbf{u}} \min_{\mathbf{v}} \mathbf{u}^T \mathbf{H} \mathbf{v} = \min_{\mathbf{v}} \max_{\mathbf{u}} \mathbf{u}^T \mathbf{H} \mathbf{v}$$

- The theorem states that knowing the other player's strategy will bring no gain in a mixed-strategy zero-sum game, and the order doesn't change the value.
- A **mixed-strategy Nash equilibrium** exists for **any two-person zero-sum game** with a finite set of actions. A Nash equilibrium in a two-player game is a pair of strategies, each of which is a best response to the other; i.e., each gives the player using it the highest possible payoff, given the other players' strategy.

- Let's consider the auxiliary game  $\Gamma_1$  first, in which the strategy of row player, i.e.,  $\mathbf{u}$ , was exposed to column player. This is of course beneficial to column player since he can select the optimal strategy  $\mathbf{v}$  to minimize  $\mathbf{u}^T \mathbf{H} \mathbf{v}$ , which is

$$\inf\{\mathbf{u}^T \mathbf{H} \mathbf{v} \mid \mathbf{v} \geq \mathbf{0}, \mathbf{1}^T \mathbf{v} = 1\} = \min_{j=1, \dots, n} (\mathbf{u}^T \mathbf{H})_j$$

- Thus row player should select  $\mathbf{u}$  to maximize the above value, which can be formulated as a linear program:

$$\begin{array}{ll} \max & \min_{j=1, \dots, n} (\mathbf{u}^T \mathbf{H})_j \\ \text{s.t.} & \mathbf{1}^T \mathbf{u} = 1 \\ & \mathbf{u} \geq \mathbf{0} \end{array}$$

# von Neumann's MINIMAX theorem: proof

- The linear program can be rewritten as below.

$$\begin{array}{ll}\max & s \\ \text{s.t.} & \mathbf{u}^T \mathbf{H} \geq s \mathbf{1}^T \\ & \mathbf{1}^T \mathbf{u} = 1 \\ & \mathbf{u} \geq \mathbf{0}\end{array}$$

- Similarly we consider the auxiliary game  $\Gamma_2$  and calculate the optimal strategy  $\mathbf{v}$  by solving the following linear program.

$$\begin{array}{ll}\min & t \\ \text{s.t.} & \mathbf{H} \mathbf{v} \leq t \mathbf{1} \\ & \mathbf{1}^T \mathbf{v} = 1 \\ & \mathbf{v} \geq \mathbf{0}\end{array}$$

- These two linear programs are both feasible and form Lagrangian dual. Thus they have the same optimal objective value according to the strong duality property.

# An example: paper-rock-scissors game

- For the paper-rock-scissors game, we have the following two linear programs.
  - Linear program for  $\Gamma_1$ :

$$\begin{array}{llllllll} \max & & s & & & & & \\ s.t. & 0u_1 & - & u_2 & + & u_3 & \geq & s \\ & u_1 & + & 0u_2 & - & u_3 & \geq & s \\ & -u_1 & + & u_2 & + & 0u_3 & \geq & s \\ & u_1 & + & u_2 & + & u_3 & = & 1 \\ & u_1, & & u_2, & & u_3 & \geq & 0 \end{array}$$

- Linear program for  $\Gamma_2$ :

$$\begin{array}{llllllll} \min & & t & & & & & \\ s.t. & 0v_1 & + & v_2 & - & v_3 & \leq & t \\ & -v_1 & + & 0v_2 & + & v_3 & \leq & t \\ & v_1 & - & v_2 & + & 0v_3 & \leq & t \\ & v_1 & + & v_2 & + & v_3 & = & 1 \\ & v_1, & & v_2, & & v_3 & \geq & 0 \end{array}$$

- The mixed strategy equilibrium is  $\mathbf{u}^T = [\frac{1}{3}, \frac{1}{3}, \frac{1}{3}]$  and  $\mathbf{u}^T = [\frac{1}{3}, \frac{1}{3}, \frac{1}{3}]$  with the game value 0.

# Comments on the mixed strategy equilibrium by von Neumann

- Note that a mixed strategy equilibrium always exists no matter whether the payoff matrix  $\mathbf{H}$  has a saddle point or not.
- Regardless of column player's selection, row player can select an appropriate strategy to guarantee his gain  $v_1 \geq 0$ .
- Regardless of row player's selection, column player can select an appropriate strategy to guarantee row player's gain  $v_1 \leq 0$ .
- Using the strategy  $\mathbf{u}^T = [\frac{1}{3}, \frac{1}{3}, \frac{1}{3}]$ , row player can guarantee that he “won't lose”, i.e., the probability of losing is less than the probability of winning.
- The strategy  $\mathbf{u}^T = [\frac{1}{3}, \frac{1}{3}, \frac{1}{3}]$  is designed for “protecting himself” rather than “attacking his opponent”, i.e., it cannot be used to benefit from opponent's fault.

### Application 3: Yao's MINIMAX principle [1977]

# Yao's MINIMAX principle

- Consider a problem  $\Pi$ . Let  $\mathcal{A} = \{A_1, A_2, \dots, A_n\}$  be algorithms to  $\Pi$ , and  $\mathcal{I} = \{I_1, I_2, \dots, I_m\}$  be the inputs with a given size. Let  $T(A_i, I_j)$  be the running time of algorithm  $A_i$  on the input  $I_j$ .

		Algorithms	
		$A_1$	$A_2$
Inputs	$I_1$	$T_{11}$	$T_{12}$
	$I_2$	$T_{21}$	$T_{22}$

- Thus  $\max_{I_j \in \mathcal{I}} T(A_i, I_j)$  represents the worst-case time for the deterministic algorithm  $A_i$ .
- For a randomized algorithms, however, it is usually difficult to bound its expected running time on worst-case inputs.
- Yao's MINIMAX principle provides a technique to build lower bound for **the expected running time of any randomized algorithm on its worst-case input**.

# Expected running time of a randomized algorithm $A_q$

- A “Las Vegas” randomized algorithm can be viewed as a distribution over all deterministic algorithms  $\mathcal{A} = \{A_1, A_2, \dots, A_n\}$ .
- Specifically, let  $q$  be a distribution over  $\mathcal{A}$ , and  $A_q$  be a randomized algorithm chosen according to  $q$ , i.e.,  $A_q$  refers to a deterministic algorithm  $A_i$  with probability  $q_i$ .
- Given a input  $I_j$ , the expected running time of  $A_q$  can be written as

$$E[T(A_q, I_j)] = \sum_{i=1}^n q_i T(A_i, I_j)$$

- Thus  $\max_{I_j \in \mathcal{I}} E[T(A_q, I_j)]$  represents the expected running time of  $A_q$  on its worst-case input.

# Expected running time of a deterministic algorithm $A_i$ on random input

- Now consider a deterministic algorithm  $A_i$  running on random input.
- Let  $p$  be a distribution over  $\mathcal{I}$ , and  $I_p$  be a random input chosen from  $\mathcal{I}$ , i.e.,  $I_p$  refers to  $I_j$  with probability  $p_j$ .
- Given a deterministic algorithm  $A_i$ , its expected running time on random input  $I_p$  can be written as

$$E[T(A_i, I_p)] = \sum_{j=1}^m p_j T(A_i, I_j)$$

- Thus  $\min_{A_i \in \mathcal{A}} E[T(A_i, I_p)]$  represents the expected running time of the best deterministic algorithm on the random input  $I_p$ .

# Yao's MINIMAX principle

## Theorem

*For any random input  $I_p$  and randomized algorithm  $A_q$ ,*

$$\min_{A_i \in \mathcal{A}} E[T(A_i, I_p)] \leq \max_{I_j \in \mathcal{I}} E[T(A_q, I_j)]$$

- To establish a lower bound for the expected running time of a randomized algorithm on its worst-case input, it suffices to find an appropriate distribution over inputs and prove that on this random input, no deterministic algorithm can do better than the randomized one.
- The power of this technique lies at the fact that one can choose any distribution over inputs and the lower bound is constructed based on deterministic algorithms.

# Yao's MINIMAX principle: proof

Proof.

$$\min_{A_i \in \mathcal{A}} E[T(A_i, I_p)] \leq \max_{u \in \Delta_m} \min_{A_i \in \mathcal{A}} E[T(A_i, I_u)] \quad (1)$$

$$= \max_{u \in \Delta_m} \min_{v \in \Delta_n} E[T(A_v, I_u)] \quad (2)$$

$$= \min_{v \in \Delta_n} \max_{u \in \Delta_m} E[T(A_v, I_u)] \quad (3)$$

$$= \min_{v \in \Delta_n} \max_{I_j \in \mathcal{I}} E[T(A_v, I_j)] \quad (4)$$

$$\leq \max_{I_j \in \mathcal{I}} E[T(A_q, I_j)] \quad (5)$$

- Here,  $\Delta_n$  denotes the set of  $n$ -dimensional probability vectors.
- Equation (3) follows by the von Neumann's MINIMAX theorem.

## Application 4: Revisiting SHORTESTPATH algorithm

# SHORTESTPATH problem

**INPUT:**  $n$  cities, and a collection of roads. A road from city  $i$  to  $j$  has a distance  $d(i, j)$ . Two specific cities:  $s$  and  $t$ .

**OUTPUT:** the shortest path from city  $s$  to  $t$ .

# SHORTESTPATH problem: PRIMAL problem

- PRIMAL problem: set variables for **roads** (Intuition:  $x_i = 0/1$  means whether edge  $i$  appears in the shortest path), and a constraint means that “we enter a node through an edge and leaves it through another edge”.

$$\begin{array}{llllllllll}
 \min & 5x_1 & + & 8x_2 & + & 1x_3 & + & 6x_4 & + & 2x_5 \\
 s.t. & x_1 & + & x_2 & & & & & & = 1 & \text{vertex } s \\
 & & & & & & & -x_4 & - & x_5 & = -1 & \text{vertex } t \\
 & -x_1 & & & + & x_3 & + & x_4 & & & = 0 & \text{vertex } u \\
 & & - & x_2 & - & x_3 & & & + & x_5 & = 0 & \text{vertex } v \\
 & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 & = 0/1
 \end{array}$$

# SHORTESTPATH problem: PRIMAL problem

- PRIMAL problem: relax the 0/1 integer linear program into linear program by the **totally uni-modular** property.

$$\begin{array}{llllllllll}
 \min & 5x_1 & + & 8x_2 & + & 1x_3 & + & 6x_4 & + & 2x_5 \\
 s.t. & x_1 & + & x_2 & & & & & & & = 1 & \text{vertex } s \\
 & & & & & & - & x_4 & - & x_5 & = -1 & \text{vertex } t \\
 & -x_1 & & & + & x_3 & + & x_4 & & & = 0 & \text{vertex } u \\
 & & - & x_2 & - & x_3 & & & + & x_5 & = 0 & \text{vertex } v \\
 & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 & \geq 0 \\
 & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 & \leq 1
 \end{array}$$

# SHORTESTPATH problem: DUAL PROBLEM

- DUAL PROBLEM: set variables for **cities**. (Intuition:  $y_i$  means the height of city  $i$ ; thus,  $y_s - y_t$  denotes the height difference between  $s$  and  $t$ , providing a lower bound of the shortest path length.)

$$\begin{array}{llllll}
 \max & y_s & - & y_t & & \\
 s.t. & y_s & & - & y_u & \leq 5 & x_1 : \text{edge } (s, u) \\
 & y_s & & & - & y_v & \leq 8 & x_2 : \text{edge } (s, v) \\
 & & & & y_u & - & y_v & \leq 1 & x_3 : \text{edge } (u, v) \\
 & & & - & y_t & + & y_u & \leq 6 & x_4 : \text{edge } (u, t) \\
 & & & - & y_t & & + & y_v & \leq 2 & x_5 : \text{edge } (v, t)
 \end{array}$$

## DUAL SIMPLEX method

# Revisiting PRIMAL SIMPLEX algorithm

- Consider the following PRIMAL problem **P**:

$$\begin{array}{llllllll}
 \min & x_1 & + & 14x_2 & + & 6x_3 & & \\
 s.t. & x_1 & + & x_2 & + & x_3 & \leq & 4 \\
 & x_1 & & & & & \leq & 2 \\
 & & & & & x_3 & \leq & 3 \\
 & & & 3x_2 & + & x_3 & \leq & 6 \\
 & x_1 & , & x_2 & , & x_3 & \geq & 0
 \end{array}$$

- PRIMAL simplex tabular:

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$	$x_6$	$x_7$
$-z = 0$	$\bar{c}_1 = 1$	$\bar{c}_2 = 14$	$\bar{c}_3 = 6$	$\bar{c}_4 = 0$	$\bar{c}_5 = 0$	$\bar{c}_6 = 0$	$\bar{c}_7 = 0$
$x_{B1} = b'_1 = 4$	1	1	1	1	0	0	0
$x_{B2} = b'_2 = 2$	1	0	0	0	1	0	0
$x_{B3} = b'_3 = 3$	0	0	1	0	0	1	0
$x_{B4} = b'_4 = 6$	0	3	1	0	0	0	1

- Primal variables:  $\mathbf{x}$ ; Feasible:  $\mathbf{B}^{-1}\mathbf{b} \geq \mathbf{0}$ .
- A basis  $\mathbf{B}$  is called **primal feasible** if all elements in  $\mathbf{B}^{-1}\mathbf{b}$  (the first column except for  $-z$ ) are non-negative.

# Revisiting PRIMAL SIMPLEX algorithm cont'd

- Now let's consider the DUAL problem **D**:

$$\begin{array}{rcll}
 \max & 4y_1 & + & 2y_2 & + & 3y_3 & + & 6y_4 \\
 s.t. & y_1 & + & y_2 & & & & & \leq & 1 \\
 & y_1 & & & & & + & 3y_4 & \leq & 14 \\
 & y_1 & & & + & y_3 & + & y_4 & \leq & 6 \\
 & y_1 & , & y_2 & , & y_3 & , & y_4 & \leq & 0
 \end{array}$$

- PRIMAL simplex tabular:

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$	$x_6$	$x_7$
$-z = 0$	$\overline{c_1} = 1$	$\overline{c_2} = 14$	$\overline{c_3} = 6$	$\overline{c_4} = 0$	$\overline{c_5} = 0$	$\overline{c_6} = 0$	$\overline{c_7} = 0$
$\mathbf{x_{B1}} = b'_1 = 4$	1	1	1	1	0	0	0
$\mathbf{x_{B2}} = b'_2 = 2$	1	0	0	0	1	0	0
$\mathbf{x_{B3}} = b'_3 = 3$	0	0	1	0	0	1	0
$\mathbf{x_{B4}} = b'_4 = 6$	0	3	1	0	0	0	1

- Dual variables:  $\mathbf{y}^T = \mathbf{c}_B^T \mathbf{B}^{-1}$ ; Feasible:  $\mathbf{y}^T \mathbf{A} \leq \mathbf{c}^T$ .
- A basis **B** is called **dual feasible** if all elements in  $\overline{\mathbf{c}}^T = \mathbf{c} - \mathbf{c}_B^T \mathbf{B}^{-1} \mathbf{A} = \mathbf{c}^T - \mathbf{y}^T \mathbf{A}$  (the first row except for  $-z$ ) are non-negative.

# Another view point of the PRIMAL SIMPLEX algorithm

- Thus another view point of the PRIMAL SIMPLEX algorithm can be described as:
  - 1 **Starting point:** The PRIMAL SIMPLEX algorithm starts with a primal feasible solution ( $\mathbf{x}_B = \mathbf{B}^{-1}\mathbf{b} \geq \mathbf{0}$ );
  - 2 **Maintenance:** Throughout the process we maintain the primal feasibility and move towards the dual feasibility;
  - 3 **Stopping criteria:**  $\bar{\mathbf{c}}^T = \mathbf{c}^T - \mathbf{c}_B^T \mathbf{B}^{-1} \mathbf{A} \geq \mathbf{0}$ , i.e.,  $\mathbf{y}^T \mathbf{A} \leq \mathbf{c}^T$ . In other words, the iteration process ends when the basis is both primal feasible and dual feasible.

# DUAL SIMPLEX works in just an opposite fashion

- DUAL SIMPLEX:

- 1 **Starting point:** The DUAL SIMPLEX algorithm starts with a dual feasible solution ( $\bar{c}^T \geq 0$ );
- 2 **Maintenance:** Throughout the process we maintain the dual feasibility and move towards the dual feasibility;
- 3 **Stopping criteria:**  $x_B = B^{-1}b \geq 0$ . In other words, the iteration process ends when the basis is both primal feasible and dual feasible.

# PRIMAL SIMPLEX vs. DUAL SIMPLEX

- Both PRIMAL SIMPLEX and DUAL SIMPLEX terminate at the same condition, i.e. the basis is both primal feasible and dual feasible.
- However, the final objective is achieved in totally opposite fashions— the PRIMAL SIMPLEX method keeps the primal feasibility while the DUAL SIMPLEX method keeps the dual feasibility during the pivoting process.
- The PRIMAL SIMPLEX algorithm *first selects an entering variable and then determines the leaving variable*.
- In contrast, the DUAL SIMPLEX method does the opposite; it *first selects a leaving variable and then determines an entering variable*.

DUAL SIMPLEX( $B_I, z, \mathbf{A}, \mathbf{b}, \mathbf{c}$ )

```
1: //DUAL SIMPLEX starts with a dual feasible basis. Here,  $B_I$  contains the
   indices of the basic variables.
2: while TRUE do
3:   if there is no index  $l$  ( $1 \leq l \leq m$ ) has  $b_l < 0$  then
4:      $\mathbf{x} = \text{CALCULATEX}(B_I, \mathbf{A}, \mathbf{b}, \mathbf{c})$ ;
5:     return ( $\mathbf{x}, z$ );
6:   end if;
7:   choose an index  $l$  having  $b_l < 0$  according to a certain rule;
8:   for each index  $j$  ( $1 \leq j \leq n$ ) do
9:     if  $a_{lj} < 0$  then
10:       $\Delta_j = -\frac{c_j}{a_{lj}}$ ;
11:     else
12:       $\Delta_j = \infty$ ;
13:     end if
14:   end for
15:   choose an index  $e$  that minimizes  $\Delta_j$ ;
16:   if  $\Delta_e = \infty$  then
17:     return 'no feasible solution';
18:   end if
19:   ( $B_I, \mathbf{A}, \mathbf{b}, \mathbf{c}, z$ ) = PIVOT( $B_I, \mathbf{A}, \mathbf{b}, \mathbf{c}, z, e, l$ );
20: end while
```

# An example

- Standard form:

$$\begin{array}{llllllll} \min & 5x_1 & + & 35x_2 & + & 20x_3 & & \\ s.t. & x_1 & - & x_2 & - & x_3 & \leq & -2 \\ & -x_1 & - & 3x_2 & & & \leq & -3 \\ & x_1 & , & x_2 & , & x_3 & \geq & 0 \end{array}$$

- Slack form:

$$\begin{array}{llllllllll} \min & 5x_1 & + & 35x_2 & + & 20x_3 & & & & \\ s.t. & x_1 & - & x_2 & - & x_3 & + & x_4 & = & -2 \\ & -x_1 & - & 3x_2 & & & & + & x_5 & = -3 \\ & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 \geq 0 \end{array}$$

# Step 1

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$
$-z = 0$	$\bar{c}_1 = 5$	$\bar{c}_2 = 35$	$\bar{c}_3 = 20$	$\bar{c}_4 = 0$	$\bar{c}_5 = 0$
$x_{B1} = b'_1 = -2$	1	-1	-1	1	0
$x_{B2} = b'_2 = -3$	-1	-3	0	0	1

- Basis (in blue):  $\mathbf{B} = \{\mathbf{a}_4, \mathbf{a}_5\}$
- Solution:  $\mathbf{x} = \begin{bmatrix} \mathbf{B}^{-1}\mathbf{b} \\ \mathbf{0} \end{bmatrix} = [0, 0, 0, -2, -3]^T$ .
- Pivoting: choose  $\mathbf{a}_5$  to leave basis since  $b'_2 = -3 < 0$ ; choose  $\mathbf{a}_1$  to enter basis since  $\min_{j, a_{2j} < 0} \frac{\bar{c}_j}{-a_{2j}} = \frac{\bar{c}_1}{-a_{21}}$ .

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$
$-z = -15$	$\bar{c}_1 = 0$	$\bar{c}_2 = 20$	$\bar{c}_3 = 20$	$\bar{c}_4 = 0$	$\bar{c}_5 = 5$
$x_{B1} = b'_1 = -5$	0	-4	-1	1	1
$x_{B2} = b'_2 = 3$	1	3	0	0	-1

- Basis (in blue):  $\mathbf{B} = \{\mathbf{a}_1, \mathbf{a}_4\}$
- Solution:  $\mathbf{x} = \begin{bmatrix} \mathbf{B}^{-1}\mathbf{b} \\ \mathbf{0} \end{bmatrix} = [3, 0, 0, -5, 0]^T$ .
- Pivoting: choose  $\mathbf{a}_4$  to leave basis since  $b'_1 = -5 < 0$ ; choose  $\mathbf{a}_2$  to enter basis since  $\min_{j, a_{1j} < 0} \frac{\bar{c}_j}{-a_{1j}} = \frac{\bar{c}_2}{-a_{12}}$ .

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$
$-z = -40$	$\bar{c}_1 = 0$	$\bar{c}_2 = 0$	$\bar{c}_3 = 15$	$\bar{c}_4 = 5$	$\bar{c}_5 = 10$
$\mathbf{x}_{B1} = b'_1 = \frac{5}{4}$	0	1	$\frac{1}{4}$	$-\frac{1}{4}$	$-\frac{1}{4}$
$\mathbf{x}_{B2} = b'_2 = -\frac{3}{4}$	1	0	$-\frac{3}{4}$	$\frac{3}{4}$	$-\frac{1}{4}$

- Basis (in blue):  $\mathbf{B} = \{\mathbf{a}_1, \mathbf{a}_2\}$
- Solution:  $\mathbf{x} = \begin{bmatrix} \mathbf{B}^{-1}\mathbf{b} \\ \mathbf{0} \end{bmatrix} = [\frac{5}{4}, -\frac{3}{4}, 0, 0, 0]^T$ .
- Pivoting: choose  $\mathbf{a}_1$  to leave basis since  $b'_2 = -\frac{3}{4} < 0$ ; choose  $\mathbf{a}_3$  to enter basis since  $\min_{j, a_{2j} < 0} \frac{\bar{c}_j}{-a_{2j}} = \frac{\bar{c}_3}{-a_{23}}$ .

# Step 4

	$x_1$	$x_2$	$x_3$	$x_4$	$x_5$
$-z = -55$	$\bar{c}_1 = 20$	$\bar{c}_2 = 0$	$\bar{c}_3 = 0$	$\bar{c}_4 = 20$	$\bar{c}_5 = 5$
$x_{B1} = b'_1 = 1$	$\frac{1}{3}$	1	0	0	$-\frac{1}{3}$
$x_{B2} = b'_2 = 1$	$-\frac{4}{3}$	0	1	-1	$\frac{1}{3}$

- Basis (in blue):  $\mathbf{B} = \{\mathbf{a}_2, \mathbf{a}_3\}$
- Solution:  $\mathbf{x} = \begin{bmatrix} \mathbf{B}^{-1}\mathbf{b} \\ \mathbf{0} \end{bmatrix} = [0, 1, 1, 0, 0]^T$ .
- Done!

# When dual simplex method is useful?

- 1 The dual simplex algorithm is most suited for problems for which an **initial dual feasible solution** is easily available.
- 2 It is particularly useful for **reoptimizing** a problem after a constraint has been added or some parameters have been changed so that the previously optimal basis is no longer feasible.
- 3 Trying dual simplex is particularly useful if your LP appears to be highly degenerate, i.e. there are many vertices of the feasible region for which the associated basis is degenerate. We may find that a large number of iterations (moves between adjacent vertices) occur with little or no improvement.<sup>2</sup>

Primal\_Dual: another IMPROVMENT approach

# Primal\_Dual method: a brief history

- In 1955, H. Kuhn proposed the Hungarian method for the MAXWEIGHTEDMATCHING problem. This method effectively explores the duality property of linear programming.
- In 1956, G. Dantzig, R. Ford, and D. Fulkerson extended this idea to solve linear programming problems.
- In 1957, R. Ford, and D. Fulkerson applied this idea to solve network-flow problem and Hitchcock problem.
- In 1957, J. Munkres applied this idea to solve the transportation problem.

# Primal\_Dual method: basic idea

# Primal\_Dual Method

- Primal\_Dual method is a dual method, which exploits the lower bound information in subsequent linear programming operations.
- Advantages:
  - 1 Unlike dual simplex starting from a **dual basic feasible solution**, primal\_dual method requires only a **dual feasible solution**.
  - 2 An optimal solution to  $DRP$  usually has combinatorial explanation, especially for graph-theory problems.

# Basic idea of primal\_dual method

- Primal P:

$$\begin{array}{llllllllll} \min & c_1x_1 & + & c_2x_2 & + & \dots & + & c_nx_n & & \\ s.t. & a_{11}x_1 & + & a_{12}x_2 & + & \dots & + & a_{1n}x_n & = & b_1 \quad (y_1) \\ & a_{21}x_1 & + & a_{22}x_2 & + & \dots & + & a_{2n}x_n & = & b_2 \quad (y_2) \\ & & & & & & & \dots & & \\ & a_{m1}x_1 & + & a_{m2}x_2 & + & \dots & + & a_{mn}x_n & = & b_m \quad (y_m) \\ & x_1 & , & x_2 & , & \dots & , & x_n & \geq & 0 \end{array}$$

- Dual D:

$$\begin{array}{llllllllll} \max & b_1y_1 & + & b_2y_2 & + & \dots & + & b_my_m & & \\ s.t. & a_{11}y_1 & + & a_{21}y_2 & + & \dots & + & a_{m1}y_m & \leq & c_1 \\ & a_{12}y_1 & + & a_{22}y_2 & + & \dots & + & a_{m2}y_m & \leq & c_2 \\ & & & & & & & \dots & & \\ & a_{1n}y_1 & + & a_{2n}y_2 & + & \dots & + & a_{mn}y_m & \leq & c_n \end{array}$$

- Basic idea: Suppose we are given a dual feasible solution  $\mathbf{y}$ . Let's verify whether  $\mathbf{y}$  is an optimal solution or not:

- 1 If  $\mathbf{y}$  is an optimal solution to the dual problem  $D$ , then the corresponding primal variables  $\mathbf{x}$  should satisfy a restricted primal problem called  $RP$ ;
- 2 Furthermore, even if  $\mathbf{y}$  is not optimal, the solution to the dual of  $RP$  (called  $DRP$ ) still provide invaluable information — it can be used to improve  $\mathbf{y}$ .

# Step 1: $y \Rightarrow x$ |

- Dual problem D:

$$\begin{array}{llllllllll} \max & b_1 y_1 & + & b_2 y_2 & + & \dots & + & b_m y_m & & \\ s.t. & a_{11} y_1 & + & a_{21} y_2 & + & \dots & + & a_{m1} y_m & \leq & c_1 & ('=\Rightarrow x_1 \geq 0) \\ & & & & & \dots & & & & & \\ & a_{1n} y_1 & + & a_{2n} y_2 & + & \dots & + & a_{mn} y_m & \leq & c_n & ('<'\Rightarrow x_n = 0) \end{array}$$

- $y$  provides information of the corresponding primal variables  $x$ :
  - 1 Given a dual feasible solution  $y$ . Let's check whether  $y$  is optimal solution or not.
  - 2 If  $y$  is optimal, we have the following restrictions on  $x$ :
$$a_{1i} y_1 + a_{2i} y_2 + \dots + a_{mi} y_m < c_i \Rightarrow x_i = 0$$
(Reason: complement slackness. An optimal solution  $y$  satisfies  $(a_{1i} y_1 + a_{2i} y_2 + \dots + a_{mi} y_m - c_i) \times x_i = 0$ )
  - 3 Let's use  $J$  to record the index of **tight constraints** where " $=$ " holds.

# Step 1: $y \Rightarrow x$ ||

$$\begin{array}{c}
 x_n = 0 \\
 \uparrow \\
 J
 \end{array}
 \begin{array}{|c|c|c|}
 \hline
 c_1 & c_2 & \dots c_n \\
 \hline
 || & || & \vee \\
 y_1 a_{11} & y_1 a_{12} & \dots y_1 a_{1n} \\
 + & + & + \\
 y_2 a_{21} & y_2 a_{22} & \dots y_2 a_{2n} \\
 + & + & + \\
 \vdots & \vdots & \vdots \\
 + & + & + \\
 y_m a_{m1} & y_m a_{m2} & \dots y_m a_{mn} \\
 \hline
 \end{array}$$

## Step 1: $y \Rightarrow x$ III

- ④ Thus the corresponding primal solution  $x$  should satisfy the following restricted primal (RP):

- ⑤ RP:

$$\begin{array}{ccccccccccc} a_{11}x_1 & + & a_{12}x_2 & + & \dots & + & a_{1n}x_n & = & b_1 \\ a_{21}x_1 & + & a_{22}x_2 & + & \dots & + & a_{2n}x_n & = & b_2 \\ & & & & \dots & & & & \\ a_{m1}x_1 & + & a_{m2}x_2 & + & \dots & + & a_{mn}x_n & = & b_m \\ & & & & & & x_i & = & 0 & i \notin J \\ & & & & & & x_i & \geq & 0 & i \in J \end{array}$$

- ⑥ In other words, the optimality of  $y$  is determined via solving  $RP$ .

# But how to solve $RP$ ? I

- $RP$ :

$$\begin{array}{ccccccccc} a_{11}x_1 & + & a_{12}x_2 & + & \dots & + & a_{1n}x_n & = & b_1 \\ a_{21}x_1 & + & a_{22}x_2 & + & \dots & + & a_{2n}x_n & = & b_2 \\ & & & & \dots & & & & \\ a_{m1}x_1 & + & a_{m2}x_2 & + & \dots & + & a_{mn}x_n & = & b_m \\ & & & & & & x_i & = & 0 \quad i \notin J \\ & & & & & & x_i & \geq & 0 \quad i \in J \end{array}$$

- How to solve  $RP$ ? Recall that  $\mathbf{Ax} = \mathbf{b}, \mathbf{x} \geq \mathbf{0}$  can be solved via solving an extended LP.

# But how to solve $RP$ ? II

- $RP$  (extended through introducing slack variables):

$$\begin{array}{llllllllll}
 \min & \epsilon = & s_1 & +s_2 & \dots & +s_m & & & & \\
 s.t. & & s_1 & & & & +a_{11}x_1 & \dots & +a_{1n}x_n & = b_1 \\
 & & & s_2 & & & +a_{21}x_1 & \dots & +a_{2n}x_n & = b_2 \\
 & & & & \dots & & & & & \\
 & & & & & s_m & +a_{m1}x_1 & \dots & +a_{mn}x_n & = b_m \\
 & & & & & & & & x_i & = 0 & i \\
 & & & & & & & & x_i & \geq 0 & i \\
 & & & & & & & & s_i & \geq 0 & \forall
 \end{array}$$

- 1 If  $\epsilon_{OPT} = 0$ , then we find a feasible solution to  $RP$ , implying that  $\mathbf{y}$  is an optimal solution;
- 2 If  $\epsilon_{OPT} > 0$ ,  $\mathbf{y}$  is not an optimal solution.

## Step 2: $\mathbf{x} \Rightarrow \Delta \mathbf{y} \mid$

- Alternatively, we can solve the dual of  $RP$ , called  $DRP$ :

$$\begin{array}{llllllllll} \max & w & = & b_1 y_1 & + & b_2 y_2 & + & \dots & + & b_m y_m \\ s.t. & & & a_{11} y_1 & + & a_{21} y_2 & + & \dots & + & a_{m1} y_m & \leq & 0 \\ & & & a_{12} y_1 & + & a_{22} y_2 & + & \dots & + & a_{m2} y_m & \leq & 0 \\ & & & & & & & \dots & & & & \\ & & & a_{1|J|} y_1 & + & a_{2|J|} y_2 & + & \dots & + & a_{m|J|} y_m & \leq & 0 \\ & & & y_1 & , & y_2 & , & & , & y_m & \leq & 1 \end{array}$$

- 1 If  $w_{OPT} = 0$ ,  $\mathbf{y}$  is an optimal solution
- 2 If  $w_{OPT} > 0$ ,  $\mathbf{y}$  is not an optimal solution. However, the optimal solution still provides useful information — the optimal solution to  $DRP$  can be used to improve  $\mathbf{y}$ .

# The difference between $DRP$ and $D$

- Dual problem  $D$ :

$$\begin{array}{llllllllll} \max & b_1 y_1 & + & b_2 y_2 & + & \dots & + & b_m y_m & & \\ s.t. & a_{11} y_1 & + & a_{21} y_2 & + & \dots & + & a_{m1} y_m & \leq & c_1 \\ & a_{12} y_1 & + & a_{22} y_2 & + & \dots & + & a_{m2} y_m & \leq & c_2 \\ & & & & & \dots & & & & \\ & a_{1n} y_1 & + & a_{2n} y_2 & + & \dots & + & a_{mn} y_m & \leq & c_n \end{array}$$

- $DRP$ :

$$\begin{array}{llllllllll} \max & w & = & b_1 y_1 & + & b_2 y_2 & + & \dots & + & b_m y_m \\ s.t. & a_{11} y_1 & + & a_{21} y_2 & + & \dots & + & a_{m1} y_m & \leq & 0 \\ & a_{12} y_1 & + & a_{22} y_2 & + & \dots & + & a_{m2} y_m & \leq & 0 \\ & & & & & \dots & & & & \\ & a_{1|J|} y_1 & + & a_{2|J|} y_2 & + & \dots & + & a_{m|J|} y_m & \leq & 0 \\ & y_1 & , & y_2 & , & & , & y_m & \leq & 1 \end{array}$$

- How to write  $DRP$  from  $D$ ?

- Replacing  $c_i$  with 0;
- Only  $|J|$  restrictions in  $DRP$ ;
- An additional restriction:  $y_1, y_2, \dots, y_m \leq 1$ ;

### Step 3: $\Delta \mathbf{y} \Rightarrow \mathbf{y} \mid$

Why  $\Delta \mathbf{y}$  can be used to improve  $\mathbf{y}$ ? Consider an improved dual solution  $\mathbf{y}' = \mathbf{y} + \theta \Delta \mathbf{y}, \theta > 0$ . We have:

- **Objective function:** Since  $\Delta \mathbf{y}^T \mathbf{b} = w_{OPT} > 0$ ,  
 $\mathbf{y}'^T \mathbf{b} = \mathbf{y}^T \mathbf{b} + \theta w_{OPT} > \mathbf{y}^T \mathbf{b}$ . In other words,  $(\mathbf{y} + \theta \Delta \mathbf{y})$  is better than  $\mathbf{y}$ .
- **Constraints:** The dual feasibility requires that:
  - For any  $j \in J$ ,  $a_{1j}\Delta y_1 + a_{2j}\Delta y_2 + \dots + a_{mj}\Delta y_m \leq 0$ . Thus we have  $\mathbf{y}'^T \mathbf{a}_j = \mathbf{y}^T \mathbf{a}_j + \theta \Delta \mathbf{y}^T \mathbf{a}_j \leq c_j$  for any  $\theta > 0$ .
  - For any  $j \notin J$ , there are two cases:

### Step 3: $\Delta \mathbf{y} \Rightarrow \mathbf{y} \parallel$

- ①  $\forall j \notin J, a_{1j}\Delta y_1 + a_{2j}\Delta y_2 + \dots + a_{mj}\Delta y_m \leq 0$ :  
Thus  $\mathbf{y}'$  is feasible for any  $\theta > 0$  since for  $\forall 1 \leq j \leq n$ ,

$$a_{1j}y'_1 + a_{2j}y'_2 + \dots + a_{mj}y'_m \quad (6)$$

$$= a_{1j}y_1 + a_{2j}y_2 + \dots + a_{mj}y_m \quad (7)$$

$$+ \theta(a_{1j}\Delta y_1 + a_{2j}\Delta y_2 + \dots + a_{mj}\Delta y_m) \quad (8)$$

$$\leq c_j \quad (9)$$

Hence dual problem  $D$  is unbounded and the primal problem  $P$  is infeasible.

- ②  $\exists j \notin J, a_{1j}\Delta y_1 + a_{2j}\Delta y_2 + \dots + a_{mj}\Delta y_m > 0$ :

We can safely set  $\theta \leq \frac{c_j - (a_{1j}y_1 + a_{2j}y_2 + \dots + a_{mj}y_m)}{a_{1j}\Delta y_1 + a_{2j}\Delta y_2 + \dots + a_{mj}\Delta y_m} = \frac{\mathbf{c}_j - \mathbf{y}^T \mathbf{a}_j}{\Delta \mathbf{y}^T \mathbf{a}_j}$

to guarantee that  $\mathbf{y}'^T \mathbf{a}_j = \mathbf{y}^T \mathbf{a}_j + \theta \Delta \mathbf{y}^T \mathbf{a}_j \leq c_j$ .

# Primal\_Dual algorithm

- 1: Infeasible = "No"  
Optimal = "No"
- $\mathbf{y} = \mathbf{y}_0$ ;      //  $\mathbf{y}_0$  is a feasible solution to the dual problem  $D$
- 2: **while** TRUE **do**
- 3:    Finding tight constraints index  $J$ , and set corresponding  $x_j = 0$   
for  $j \notin J$ .
- 4:    Thus we have a smaller RP.
- 5:    Solve DRP. Denote the solution as  $\Delta \mathbf{y}$ .
- 6:    **if** DRP objective function  $w_{OPT} = 0$  **then**
- 7:     Optimal = "Yes"
- 8:     **return**  $\mathbf{y}$ ;
- 9:    **end if**
- 10:   **if**  $\Delta \mathbf{y}^T \mathbf{a}_j \leq 0$  (for all  $j \notin J$ ) **then**
- 11:     Infeasible = "Yes";
- 12:     **return** ;
- 13:   **end if**
- 14:   Set  $\theta = \min \frac{c_j - \mathbf{y}^T \mathbf{a}_j}{\Delta \mathbf{y}^T \mathbf{a}_j}$  for  $\Delta \mathbf{y}^T \mathbf{a}_j > 0, j \notin J$ .
- 15:   Update  $\mathbf{y}$  as  $\mathbf{y} = \mathbf{y} + \theta \Delta \mathbf{y}$ ;
- 16: **end while**

# Advantages of Primal\_Dual algorithm

- Some facts:
  - Primal\_dual algorithm ends if using anti-cycling rule.  
(Reason: the objective value  $\mathbf{y}^T \mathbf{b}$  increases if there is no degeneracy.)
  - Both  $RP$  and  $DRP$  do not explicitly rely on  $\mathbf{c}$ . In fact, the information of  $\mathbf{c}$  is represented in  $J$ .
  - This leads to another advantage of primal\_dual technique, i.e.,  $RP$  is usually a purely combinatorial problem. Take `SHORTESTPATH` as an example.  $RP$  corresponds to a “connection” problem.
  - More and more constraints become tight in the primal\_dual process.

(See Lecture 10 for a primal\_dual algorithm for `MAXIMUMFLOW` problem. )

SHORTESTPATH: Dijkstra's algorithm is essentially Primal\_Dual algorithm

# SHORTEST PATH problem

- PRIMAL problem: relax the 0/1 integer linear program into linear program by the **totally uni-modular** property.

$$\begin{array}{llllllllll}
 \min & 5x_1 & + & 8x_2 & + & 1x_3 & + & 6x_4 & + & 2x_5 \\
 s.t. & x_1 & + & x_2 & & & & & & & = 1 & \text{vertex } s \\
 & & & & & & & -x_4 & - & x_5 & = -1 & \text{vertex } t \\
 & -x_1 & & & + & x_3 & + & x_4 & & & = 0 & \text{vertex } u \\
 & & - & x_2 & - & x_3 & & & + & x_5 & = 0 & \text{vertex } v \\
 & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 & \geq 0 \\
 & x_1 & , & x_2 & , & x_3 & , & x_4 & , & x_5 & \leq 1
 \end{array}$$

# Dual of SHORTESTPATH problem

- DUAL PROBLEM: set variables for **cities**. (Intuition:  $y_i$  means the height of city  $i$ ; thus,  $y_s - y_t$  denotes the height difference between  $s$  and  $t$ , providing a lower bound of the shortest path length.)

$$\begin{array}{llllll}
 \max & y_s & - & y_t & & \\
 s.t. & y_s & & - & y_u & \leq 5 \quad x_1 : \text{edge } (s, u) \\
 & y_s & & & - & y_v \leq 8 \quad x_2 : \text{edge } (s, v) \\
 & & & y_u & - & y_v \leq 1 \quad x_3 : \text{edge } (u, v) \\
 & & - & y_t & + & y_u \leq 6 \quad x_4 : \text{edge } (u, t) \\
 & & - & y_t & & + & y_v \leq 2 \quad x_5 : \text{edge } (v, t)
 \end{array}$$

# A simplified version

- DUAL PROBLEM: simplify by setting  $y_t = 0$  (and remove the 2nd constraint in the primal problem  $P$ , accordingly)

$$\begin{array}{llllll} \max & y_s & & & & \\ s.t. & y_s & - & y_u & \leq 5 & x_1 : \text{edge } (s, u) \\ & y_s & & & & \\ & & & - & y_v & \leq 8 & x_2 : \text{edge } (s, v) \\ & & y_u & - & y_v & \leq 1 & x_3 : \text{edge } (u, v) \\ & & y_u & & & \leq 6 & x_4 : \text{edge } (u, t) \\ & & & y_v & \leq 2 & x_5 : \text{edge } (v, t) \end{array}$$

# Iteration 1 I

- Dual feasible solution:  $\mathbf{y}^T = (0, 0, 0)$ . Let's check the constraints in  $D$ :

$$\begin{array}{rclcl}
 y_s & - & y_u & < & 5 \Rightarrow x_1 = 0 \\
 y_s & & & - & y_v < 8 \Rightarrow x_2 = 0 \\
 & & y_u & - & y_v < 1 \Rightarrow x_3 = 0 \\
 & & y_u & & < 6 \Rightarrow x_4 = 0 \\
 & & & y_v < 2 \Rightarrow x_5 = 0
 \end{array}$$

- Identifying tight constraints in  $D$ :  $J = \Phi$ , implying that  $x_1, x_2, x_3, x_4, x_5 = 0$ .

- RP:

$$\begin{array}{llllllll}
 \min & s_1 & +s_2 & +s_3 & & & & \\
 s.t. & s_1 & & & +x_1 & +x_2 & & = 1 \quad \text{node } s \\
 & & s_2 & & -x_1 & & +x_3 & +x_4 = 0 \quad \text{node } u \\
 & & & s_3 & & -x_2 & -x_3 & +x_5 = 0 \quad \text{node } v \\
 & s_1, & s_2, & s_3, & & & & \geq 0 \\
 & & & & x_1, & x_2, & x_3, & x_4, & x_5 = 0
 \end{array}$$

- *DRP*:

$$\begin{array}{ll}
 \max & y_s \\
 \text{s.t.} & y_s \leq 1 \\
 & y_u \leq 1 \\
 & y_v \leq 1
 \end{array}$$

- Solve *DRP* using combinatorial technique: optimal solution  $\Delta \mathbf{y}^T = (1, 0, 0)$ . *Note: the optimal solution is not unique*
- Step length  $\theta$ :  $\theta = \min\left\{\frac{\mathbf{c}_1 - \mathbf{y}^T \mathbf{a}_1}{\Delta \mathbf{y}^T \mathbf{a}_1}, \frac{\mathbf{c}_2 - \mathbf{y}^T \mathbf{a}_2}{\Delta \mathbf{y}^T \mathbf{a}_2}\right\} = \min\{5, 8\} = 5$
- Update  $\mathbf{y}$ :  $\mathbf{y}^T = \mathbf{y}^T + \theta \Delta \mathbf{y}^T = (5, 0, 0)$ .

- From the point of view of Dijkstra's algorithm:
  - Optimal solution to  $DRP$  is  $\Delta \mathbf{y}^T = (1, 0, 0)$ : the explored vertex set  $S = \{s\}$  in Dijkstra's algorithm. In fact,  $DRP$  is solved via identifying the nodes reachable from  $s$ .
  - Step length  $\theta = \min\{\frac{c_1 - \mathbf{y}^T \mathbf{a}_1}{\Delta \mathbf{y}^T \mathbf{a}_1}, \frac{c_2 - \mathbf{y}^T \mathbf{a}_2}{\Delta \mathbf{y}^T \mathbf{a}_2}\} = \min\{5, 8\} = 5$ : finding the closest vertex to the nodes in  $S$  via comparing all edges going out from  $S$ .

# Iteration 2 I

- Dual feasible solution:  $\mathbf{y}^T = (5, 0, 0)$ . Let's check the constraints in  $D$ :

$$\begin{array}{rclclcl}
 y_s & - & y_u & = & 5 & & \\
 y_s & & & - & y_v & < & 8 \Rightarrow x_2 = 0 \\
 & & y_u & - & y_v & < & 1 \Rightarrow x_3 = 0 \\
 & & & & y_u & < & 6 \Rightarrow x_4 = 0 \\
 & & & & & y_v & < & 2 \Rightarrow x_5 = 0
 \end{array}$$

- Identifying tight constraints in  $D$ :  $J = \{1\}$ , implying that  $x_2, x_3, x_4, x_5 = 0$ .
- RP:

$$\begin{array}{rclclcl}
 \min & s_1 & +s_2 & +s_3 & & & \\
 s.t. & s_1 & & & +x_1 & +x_2 & = 1 \quad \text{node } s \\
 & & s_2 & & -x_1 & & +x_3 & +x_4 & = 0 \quad \text{node } u \\
 & & & s_3 & & -x_2 & -x_3 & & +x_5 & = 0 \quad \text{node } v \\
 & s_1, & s_2, & s_3, & & & & & & \geq 0 \\
 & & & & & x_2, & x_3, & x_4, & x_5 & = 0
 \end{array}$$

- *DRP*:

$$\begin{array}{ll} \max & y_s \\ \text{s.t.} & y_s - y_u \leq 0 \\ & y_s, y_u, y_v \leq 1 \end{array}$$

- Solve *DRP* using combinatorial technique: optimal solution  $\Delta \mathbf{y}^T = (1, 1, 0)$ . *Note: the optimal solution is not unique*
- Step length  $\theta$ :  

$$\theta = \min \left\{ \frac{c_2 - \mathbf{y}^T \mathbf{a}_2}{\Delta \mathbf{y}^T \mathbf{a}_2}, \frac{c_3 - \mathbf{y}^T \mathbf{a}_3}{\Delta \mathbf{y}^T \mathbf{a}_3}, \frac{c_4 - \mathbf{y}^T \mathbf{a}_4}{\Delta \mathbf{y}^T \mathbf{a}_4} \right\} = \min \{3, 1, 6\} = 1$$
- Update  $\mathbf{y}$ :  $\mathbf{y}^T = \mathbf{y}^T + \theta \Delta \mathbf{y}^T = (6, 1, 0)$ .

- From the point of view of Dijkstra's algorithm:
  - Optimal solution to  $DRP$  is  $\Delta \mathbf{y}^T = (1, 1, 0)$ : the explored vertex set  $S = \{s, u\}$  in Dijkstra's algorithm. In fact,  $DRP$  is solved via identifying the nodes reachable from  $s$ .
  - Step length  

$$\theta = \min \left\{ \frac{\mathbf{c}_2 - \mathbf{y}^T \mathbf{a}_2}{\Delta \mathbf{y}^T \mathbf{a}_2}, \frac{\mathbf{c}_3 - \mathbf{y}^T \mathbf{a}_3}{\Delta \mathbf{y}^T \mathbf{a}_3}, \frac{\mathbf{c}_4 - \mathbf{y}^T \mathbf{a}_4}{\Delta \mathbf{y}^T \mathbf{a}_4} \right\} = \min \{3, 1, 6\} = 1:$$
 finding the closest vertex to the nodes in  $S$  via comparing all edges going out from  $S$ .

# Iteration 3 I

- Dual feasible solution:  $\mathbf{y}^T = (6, 1, 0)$ . Let's check the constraints in  $D$ :

$$\begin{array}{rclcl}
 y_s & - & y_u & = & 5 \\
 y_s & & & - & y_v < 8 \Rightarrow x_2 = 0 \\
 & & y_u & - & y_v = 1 \\
 & & y_u & & < 6 \Rightarrow x_4 = 0 \\
 & & & & y_v < 2 \Rightarrow x_5 = 0
 \end{array}$$

- Identifying tight constraints in  $D$ :  $J = \{1, 3\}$ , implying that  $x_2, x_4, x_5 = 0$ .
- RP:

$$\begin{array}{rcll}
 \min & s_1 & +s_2 & +s_3 \\
 s.t. & s_1 & & & +x_1 & +x_2 & & = 1 & \text{node } s \\
 & & s_2 & & -x_1 & & +x_3 & +x_4 & = 0 & \text{node } u \\
 & & & s_3 & & -x_2 & -x_3 & & +x_5 & = 0 & \text{node } v \\
 & s_1, & s_2, & s_3, & & & & & & \geq 0 \\
 & & & & x_2, & & x_4, & & x_5 & = 0
 \end{array}$$

- *DRP*:

$$\begin{array}{llll}
 \max & y_s & & \\
 \text{s.t.} & y_s - y_u & & \leq 0 \\
 & & y_u - y_v & \leq 0 \\
 & y_s, & y_u, & y_v \leq 1
 \end{array}$$

- Solve *DRP* using combinatorial technique: optimal solution  $\Delta \mathbf{y}^T = (1, 1, 1)$ . *Note: the optimal solution is not unique*
- Step length  $\theta$ :  $\theta = \min\left\{\frac{\mathbf{c}_4 - \mathbf{y}^T \mathbf{a}_4}{\Delta \mathbf{y}^T \mathbf{a}_4}, \frac{\mathbf{c}_5 - \mathbf{y}^T \mathbf{a}_5}{\Delta \mathbf{y}^T \mathbf{a}_5}\right\} = \min\{5, 2\} = 2$
- Update  $\mathbf{y}$ :  $\mathbf{y}^T = \mathbf{y}^T + \theta \Delta \mathbf{y}^T = (8, 3, 2)$ .

- From the point of view of Dijkstra's algorithm:
  - Optimal solution to  $DRP$  is  $\Delta \mathbf{y}^T = (1, 1, 1)$ : the explored vertex set  $S = \{s, u, v\}$  in Dijkstra's algorithm. In fact,  $DRP$  is solved via identifying the nodes reachable from  $s$ .

- Step length  $\theta = \min\left\{\frac{c_4 - \mathbf{y}^T \mathbf{a}_4}{\Delta \mathbf{y}^T \mathbf{a}_4}, \frac{c_5 - \mathbf{y}^T \mathbf{a}_5}{\Delta \mathbf{y}^T \mathbf{a}_5}\right\} = \min\{5, 2\} = 2$ :  
finding the closest vertex to the nodes in  $S$  via comparing all edges going out from  $S$ .

# Iteration 4 I

- Dual feasible solution:  $\mathbf{y}^T = (8, 3, 2)$ . Let's check the constraints in  $D$ :

$$\begin{array}{rclcl}
 y_s & - & y_u & = & 5 \\
 y_s & & & - & y_v < 8 \Rightarrow x_2 = 0 \\
 & & y_u & - & y_v = 1 \\
 & & y_u & & < 6 \Rightarrow x_4 = 0 \\
 & & & & y_v = 2
 \end{array}$$

- Identifying tight constraints in  $D$ :  $J = \{1, 3, 5\}$ , implying that  $x_2, x_4 = 0$ .
- RP:

$$\begin{array}{llllllllll}
 \min & s_1 & +s_2 & +s_3 & & & & & & \\
 s.t. & s_1 & & & +x_1 & +x_2 & & & = 1 & \text{node } s \\
 & & s_2 & & -x_1 & & +x_3 & +x_4 & = 0 & \text{node } u \\
 & & & s_3 & & -x_2 & -x_3 & & +x_5 & = 0 & \text{node } v \\
 & s_1, & s_2, & s_3, & & & & & & \geq 0 \\
 & & & & x_2, & & & & & = 0 \\
 & & & & & x_4 & & & & = 0
 \end{array}$$

- *DRP*:

$$\begin{array}{llll}
 \max & y_s & & \\
 s.t. & y_s - y_u & & \leq 0 \\
 & & y_u - y_v & \leq 0 \\
 & & & y_v \leq 0 \\
 & y_s, & y_u, & y_v \leq 1
 \end{array}$$

- Solve *DRP* using combinatorial technique: optimal solution  $\Delta \mathbf{y}^T = (0, 0, 0)$ . Done!

- From the point of view of Dijkstra's algorithm:
  - Optimal solution to  $DRP$  is  $\Delta \mathbf{y}^T = (0, 0, 0)$ : there is a path from  $s$  to  $t$ , forcing  $y_s = 0$  (note  $y_t$  is fixed to be 0). This corresponds to the explored node set  $S = \{s, u, v, t\}$  in Dijkstra's algorithm.
- Another intuitive explanation: the **tightest** rope when picking up  $s$ .
